## Event sequence vs other series

### Event data vs time series?

# Joint end-to-end learning

## Event data for point process

#### A variety of applications

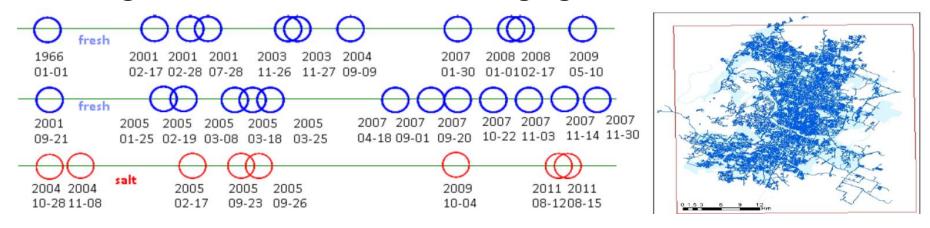

- infection and spread of contagious diseases (spatial info)
- sequence of retweets in Tweeter (spatial info)
- sequence of user queries submitted to a search engine (content info)
- earthquakes with magnitudes with locations: spatial-temporal event modeling

#### Goals of temporal event modeling

- studying the mechanisms that give rise to the dynamics of the recurrence of events
- predicting the dynamics of events in the future based on event history
- designing intervention and control measures to steer the dynamics of events to desirable outcomes

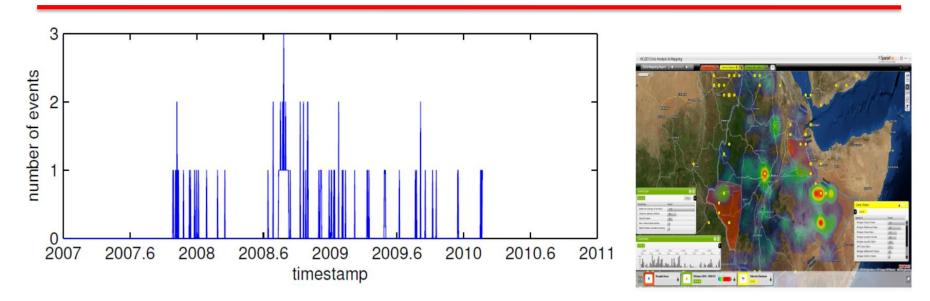

### Underground Water Pipe Failure Data

#### Management and maintenance of aging infrastructures

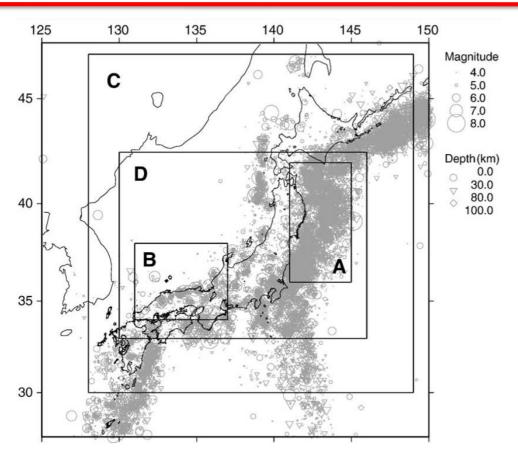

- ► 700K underground water pipes of a large Asian city: preventative rehabilitation and replacement are the key activities for pipe asset management
- Understanding of the failure mechanism in repairable pipes and modeling the stochastic behavior of the recurrences of pipe failure

### Armed Conflict Location and Event Data (ACLED)

- ▶ 36.3% dyadic events in the Afghan dataset are without the actor information
- an event with civilian casualty is observed but we did not observe who carried out the act
- ► Event attribution: infer the missing actors of events of which only the timestamps are known based on retaliation patterns [Zammit, et al. 2012]

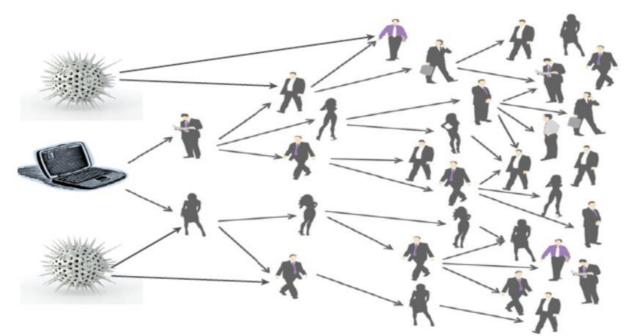

#### Space-time Point Process Models for Earthquake(ETAS)

event sequences with space and magnitude information [Ogata, 1988]. Ogata, Y. (1988). Statistical models for earthquake occurrences and residual analysis for point processes. J. Amer. Statist. Assoc. 83 9–27.

## Event data for point process

#### Conditional intensity

## Classical model of point process

### Poisson processes:

$$\lambda^*(t) = \lambda$$

### Terminating point processes:

$$\lambda^*(t) = g^*(t)(1 - N(t))$$

### Self-exciting (Hawkes) point processes:

$$\lambda^*(t) = \mu + \alpha \sum_{t_i \in \mathcal{H}(t)} \kappa_{\omega}(t - t_i)$$

### Self-correcting processes:

$$\lambda^*(t) = e^{\mu t - \sum_{t_i \in \mathcal{H}(t)} \alpha}$$

## Multi-dimensional Hawkes process

▶ Intensity of multi-dimensional Hawkes process: given event data  $\{(t_i^m)_i\}_{m=1}^M$ 

$$\lambda_d = \mu_d + \sum_{i:t_i < t} \alpha_{dd_i} e^{-\beta(t - t_i)}$$

- where  $\mu_d \ge 0$  is the base intensity for the d-th Hawkes process
- The coefficient  $\alpha_{dd_i}$  captures the mutually exciting property between the  $d_i$ -th and the d-th dimension. It shows how much influence the events in  $d_i$ -th process have on future events in the d-th process.

### Maximum-likelihood estimation for MHP

#### log-likelihood:

$$\begin{split} \log L &= \sum_{d=1}^{M} \left\{ \sum_{(t_{i},d_{i})|d_{i}=d} \log \lambda_{d_{i}}(t_{i}) - \int_{0}^{T} \lambda_{d}(t)dt \right\} \\ &= \sum_{i=1}^{n} \log \left( \mu_{d_{i}} + \sum_{t_{j} < t_{i}} \alpha_{d_{i}d_{j}} e^{-\beta(t_{i}-t_{j})} \right) - T \sum_{d=1}^{M} \mu_{d} - \sum_{d=1}^{M} \sum_{j=1}^{n} \alpha_{dd_{j}} G_{dd_{j}}(T - t_{j}) \end{split}$$

Jensen equality

$$\geq \sum_{i=1}^{n} \left( p_{ii} \log \frac{\mu_{d_i}}{p_{ii}} + \sum_{j=1}^{i-1} p_{ij} \log \frac{\alpha_{d_i d_j} e^{-\beta(t_i - t_j)}}{p_{ij}} \right) - T \sum_{d=1}^{M} \mu_d - \sum_{d=1}^{M} \sum_{j=1}^{n} \alpha_{dd_j} G_{dd_j} (T - t_j)$$

$$= Q(\theta | \theta^l)$$

EM algorithm

[Zhou et al 2013]

Learning Social Infectivity in Sparse Low-rank Networks Using Multi-dimensional Hawkes Processes. In AISTATS 2013

## Maximum-likelihood estimation

#### So for E-step

$$p_{ii}^{(k+1)} = \frac{\mu_{d_i}^{(k)}}{\mu_{d_i}^{(k)} + \sum_{j=1}^{i-1} \alpha_{d_i d_j}^{(k)} e^{-\beta(t_i - t_j)}}$$

$$p_{ij}^{(k+1)} = \frac{\alpha^{(k)} e^{-\beta(t_i - t_j)}}{\mu_{d_i}^{(k)} + \sum_{j=1}^{i-1} \alpha_{d_i d_j}^{(k)} e^{-\beta(t_i - t_j)}} = \frac{\alpha^{(k)} e^{-\beta(t_i - t_j)}}{\mu_{d_i}^{(k)} + \sum_{j=1}^{i-1} \alpha_{d_i d_j}^{(k)} e^{-\beta(t_i - t_j)}} = \frac{\alpha^{(k)} e^{-\beta(t_i - t_j)}}{\alpha^{(k)} e^{-\beta(t_i - t_j)}}$$

The probability that the event i is triggered by the base intensity  $\mu$ 

The probability that the event i is triggered by the event j

## Maximum-likelihood estimation

M-step (do partial differential equation for  $\mu$  and  $\alpha$ )

$$\mu_d^{(k+1)} = \frac{1}{T} \sum_{i=1,d_i=d}^n p_{ii}^{(k+1)}$$

$$\alpha_{uv}^{(k+1)} = \frac{\sum_{i=1,d_i=u}^n \sum_{j=1,d_j=v}^{i-1} p_{ij}^{(k+1)}}{\sum_{j=1,d_j=v}^n G(T-t_j)}$$

For  $\beta$ , if  $e^{-\beta(T-t_i)} \approx 0$ 

$$\beta^{(k+1)} = \frac{\sum_{i>j} p_{ij}^{(k+1)}}{\sum_{i>j} (t_i - t_j) p_{ij}^{(k+1)}}$$

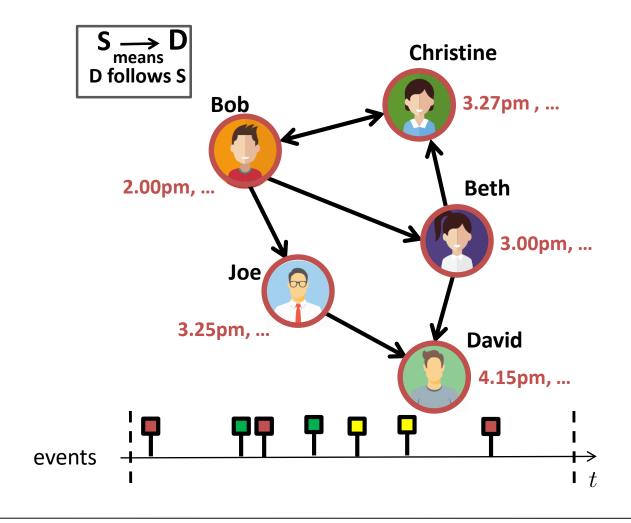

## **Application**

- For  $\alpha_{ij}$ , influence from dimension i to j
- Social Infectivity
- ▶ If high dimension, overfitting for  $A = [\alpha_{ij}]$
- Sparse Low-rank Networks [1]
- regularize the maximum likelihood estimator  $\min_{A \ge 0, \mu \ge 0} -L(A, \mu) + \lambda_1 ||A||_* + \lambda_2 ||A||_1$
- ▶  $||A||_*$  is the nuclear norm of matrix A, which is defined to be the sum of its singular value

[Zhou et al 2013]

[1] Learning Social Infectivity in Sparse Low-rank Networks Using Multi-dimensional Hawkes Processes. In AISTATS 2013

### Information propagation with MHP

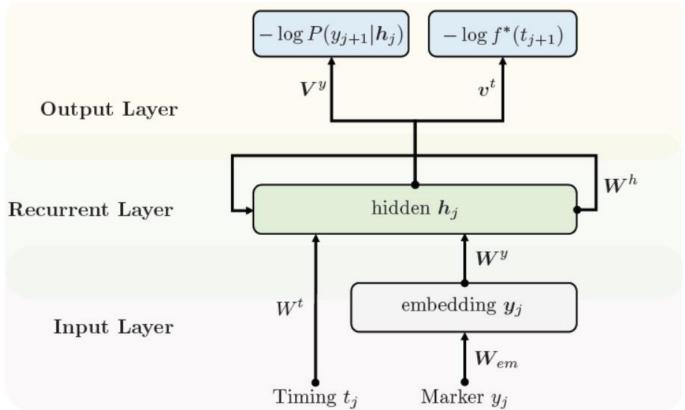

### Outline

- 1. introduction of point process
- 2. classic statistical learning of TPP
- 3. Deep learning for TPP
- 4. Adversarial learning for TPP
- 5. Reinforcement learning for TPP
- 6. Embedding for multi-dimensional TPP

- ▶ In traditional way, you have to design the marked conditional intensity (or the temporal conditional intensity and density for the marked data) and find its tailored learning algorithm.
- But in deep point process, it is much easier while using RNN (or LSTM and other deep model).

f\*: conditional density function

**Architect** 

[Nan et al 2016]

Recurrent marked temporal point processes: Embedding event history to vector. In KDD, 2016.

- For time prediction
- ► The simplest: Gaussian distribution (MSE)

$$f(t_{j+1}|h_j) = \frac{1}{\sqrt{2\pi\sigma}} \exp\left(\frac{-(t_{j+1} - \tilde{t}_{j+1})^2}{2\sigma^2}\right)$$

- $bildet ilde t_{j+1}$ : the real timestamp of j+1
- Shortcoming 1: can not get its analytical intensity
- Shortcoming 2: the distribution of  $t_{j+1}$  has a probability that  $t_{j+1} < t_j$

- So other conditional assumptions besides Gaussian distribution is OK such as exponential distribution.
- Method 2 for time prediction: intensity assumption
- ► For example with intensity based on three terms:

$$\lambda^*(t) = \exp(\mathbf{v}^{\mathbf{T}} \cdot \mathbf{h}_j + w(t - t_j) + b)$$
past influence current influence base intensity

► The first term: represents the accumulative influence from the marker and the timing information of the past events

$$\lambda^*(t) = \exp(\mathbf{v^T} \cdot \mathbf{h}_j + w(t - t_j) + b)$$

past current base influence intensity

- ► The second term emphasizes the influence of the current event j
- ► The last term gives a base intensity level for the occurrence of the next event.
- ► The exponential function outside acts as a non-linear transformation and guarantees that the intensity is positive.

MLE for Marked RNN Point Process

$$L = \prod_{j=1}^{n} f(t_{j+1}, y_{j+1} | \mathbf{h}_{j}) = \prod_{j=1}^{n} f(t_{j+1} | \mathbf{h}_{j}) \cdot P(y_{j+1} | \mathbf{h}_{j})$$

$$\implies \log L = \sum_{j=1}^{n} f(t_{j+1} | \mathbf{h}_{j}) + \sum_{j=1}^{n} P(y_{j+1} | \mathbf{h}_{j})$$

$$-\log P(y_{j+1} | h_{j}) \qquad -\log f^{*}(t_{j+1}) \qquad -\log f^{*}(t_{j+1}) \qquad -\log f^{*}(t_{j+2})$$

$$\downarrow \mathbf{h}_{j-1} \qquad \qquad \mathbf{h}_{j-1} \qquad \qquad \mathbf{h}_{j-1} \qquad \mathbf{h}_{j-1}$$

▶ The density  $f^*(t)$  for event j + 1

$$f^*(t) = f(t|h_j) = \lambda^*(t) \exp(-\int_{t_j}^t \lambda^*(\tau) d\tau)$$
  
=  $\exp\{\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + w(t - t_j) + b - \frac{1}{w} (\exp(\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + w(t - t_j) + b) - \exp(v^T \cdot h_j + b))\}$ 

▶ Prediction method 1: the exception of  $t_{j+1}$ 

$$\hat{t}_{j+1} = \int_{t_j}^{\infty} t f^*(t) dt$$

Can not get the analytical result and only numerical integration techniques can be used.

- Prediction method 2: the simulation way
- Recall the inversed method

For a temporal point process  $\{t_1, t_2, ..., t_n\}$  with conditioned intensity  $\lambda^*(t)$  and integrated conditional intensity as:

$$\Lambda(t) = \int_0^t \lambda^*(\tau) d\tau$$

Then  $\{\Lambda(t_j)\}$  is a Poisson process with unit intensity. In other words, the integrated conditional intensity between inter-event time

 $\Lambda_{t_j}(t_{j+1}) \coloneqq \Lambda(t_j, t_{j+1}) = \Lambda(t_{j+1}) - \Lambda(t_j)$ 

is exponentially distributed with parameter 1.

- So if given timestamp  $t_j$  and function  $\Lambda_{t_j}(t_{j+1})$  is known Then we can predict  $t_{j+1}$  with the inversed method
- Given  $s \sim Exp(1)$  (i.e.  $s = -\log(1 u)$ ,  $u \sim uniform(0,1)$ ) then

$$\hat{t}_{j+1} = \Lambda_{t_j}^{-1}(s)$$

Apparently  $\Lambda_{t_j}(t_{j+1}) = \Lambda(t_j, t_{j+1})$  satisfies that

$$s = \Lambda(t_j, t_{j+1}) = \frac{1}{w} (\exp(\mathbf{v}^T \cdot \mathbf{h}_j + w(t_{j+1} - t_j) + b) - \exp(\mathbf{v}^T \cdot \mathbf{h}_j + b)) = -\log(1 - u)$$

Then

$$\hat{t}_{j+1} = t_j + \frac{\log(\exp(\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + b) - w\log(1 - u)) - (\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + b)}{w}$$

### Marked RNN Point Process

▶ Median sampling when u = 0.5

$$\hat{t}_{j+1} = t_j + \frac{\log(\exp(\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + b) + w\log(2)) - (\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + b)}{w}$$

lacktriangle Quantile Interval Estimation. Given significance  $\alpha$ 

$$\hat{t}_{j+1}^{(\frac{\alpha}{2})} = t_j + \frac{\log(\exp(\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + b) - w\log(1 - \frac{\alpha}{2})) - (\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + b)}{w}$$

$$\hat{t}_{j+1}^{(1-\frac{\alpha}{2})} = t_j + \frac{\log(\exp(\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + b) - w\log(\frac{\alpha}{2})) - (\mathbf{v}^{\mathsf{T}} \cdot \mathbf{h}_j + b)}{w}$$

For example, when given significance  $\alpha = 0.1$ , it means that there is 90% that the event  $t_{j+1}$  is in the interval  $[\hat{t}_{j+1}^{(\frac{\alpha}{2})}, \hat{t}_{j+1}^{(1-\frac{\alpha}{2})}]$  in theory.

## Outline

- 1. Introduction of point process
- 2. Classic statistical learning of TPP
- 3. Wasserstein adversarial learning for TPP
- 4. Reinforcement learning for TPP
- 5. Embedding for multi-dimensional TPP

### Wasserstein-Distance for PP

The Wasserstein distance between distribution of two point processes is:

$$W_1(P_r, P_g) = \inf_{\psi \in \Psi(P_r, P_g)} E_{\{\xi, \rho\} \sim \psi}[\|\xi - \rho\|_*]$$

 $\Psi$  denotes the set of all joint distributions whose marginals are  $P_r$ ,  $P_g$ .

The distance between two sequences  $\|\xi - \rho\|_*$  need further attention. Take  $\xi = \{x_1, \dots, x_n\}$ ,  $\rho = \{y_1, \dots, y_m\}$  and with a permutation  $\sigma$ , w.l.o.g. assuming  $n \leq m$ 

$$\|\xi - \rho\|_* = \min_{\sigma} \sum_{i=1}^n \|x_i - y_{\sigma(i)}\| + \sum_{i=n+1}^m \|s - y_{\sigma(i)}\|$$

s is a fixed limiting point in border

[Xiao et al 2017]

[1] Wasserstein learning of deep generative point process models. In NIPS, 2017.

# $\|\xi - \rho\|_*$ is a distance

- It is obvious in nonnegative and symmetric
- ▶ triangle inequality : assume  $\xi = \{x_1, ..., x_n\}$  ,  $\rho = \{y_1, ..., y_k\}$  and  $\varsigma = \{z_1, ..., z_m\}$  where  $n \le k \le m$ , define the permutation

$$\hat{\sigma} := \arg\min_{\sigma} \sum_{i=1}^{n} \|x_i - y_{\sigma(i)}\| + \sum_{i=n+1}^{k} \|s - y_{\sigma(i)}\|$$

We know that

$$\|\xi - \rho\|_{\star} = \sum_{i=1}^{n} \|x_i - y_{\hat{\sigma}(i)}\| + \sum_{i=n+1}^{k} \|s - y_{\hat{\sigma}(i)}\|$$

# $\|\xi - \rho\|_*$ is a distance

Therefore, we have that

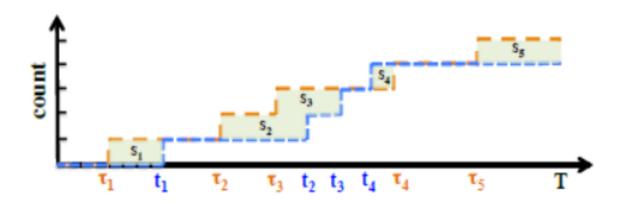

$$\begin{split} \|\xi - \zeta\|_{\star} &= \min_{\sigma} \sum_{i=1}^{n} \|x_{i} - z_{\sigma(i)}\| + \sum_{i=n+1}^{m} \|s - z_{\sigma(i)}\| \\ &\leq \min_{\sigma} \sum_{i=1}^{n} \left( \|x_{i} - y_{\hat{\sigma}(i)}\| + \|y_{\hat{\sigma}(i)} - z_{\sigma(i)}\| \right) + \sum_{i=n+1}^{k} \left( \|s - y_{\hat{\sigma}(i)}\| + \|y_{\hat{\sigma}(t)} - z_{\sigma(i)}\| \right) \\ &+ \sum_{i=k+1}^{m} \|s - z_{\sigma(i)}\| \\ &= \|\xi - \rho\|_{\star} + \min_{\sigma} \sum_{i=1}^{k} \|y_{\hat{\sigma}(i)} - z_{\sigma(i)}\| + \sum_{i=k+1}^{m} \|s - z_{\sigma(i)}\| \\ &= \|\xi - \rho\|_{\star} + \min_{\sigma} \sum_{i=1}^{k} \|y_{i} - z_{\sigma(\hat{\sigma}^{-1}(i))}\| + \sum_{i=k+1}^{m} \|s - z_{\sigma(i)}\| \\ &= \|\xi - \rho\|_{\star} + \|\rho - \zeta\|_{\star} \end{split}$$

Same on the real line

#### Wasserstein-Distance for TPP

Interestingly, in the case of temporal point process in [0,T] for  $\xi = \{t_1, ..., t_n\}$ ,  $\rho = \{\tau_1, ..., \tau_m\}$  is reduced to

$$\|\xi - \rho\|_* = \sum_{i=1}^n |t_i - \tau_i| + (m-n) \times T - \sum_{i=n+1}^m \tau_i$$

 $\|\cdot\|_*$  distance between sequences

### Wasserstein-Distance for TPP

Dual Wasserstein distance (event sequence):

$$W_1(P_r, P_g) = \sup_{\|f\|_{L} \le 1} E_{\{\xi, \rho\} \sim P_r}[f(\xi)] - E_{\rho \sim P_g}[f(\rho)]$$

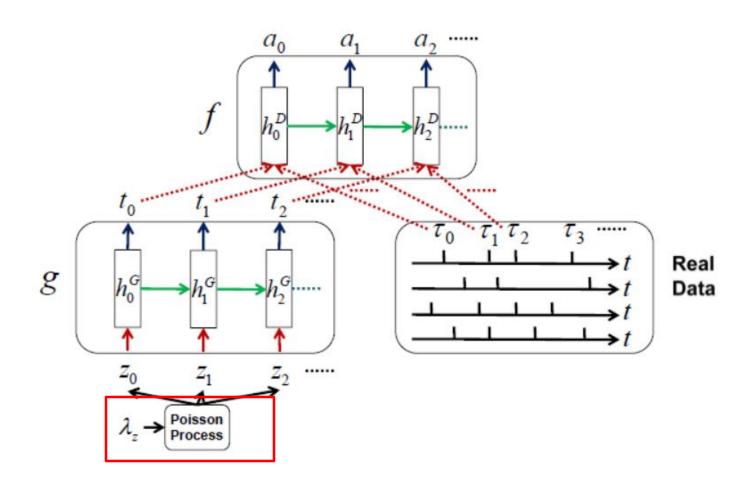

Choose a parametric family of functions  $f_w$  to approximate f

$$\max_{w \in W, ||f_w||_{L} \le 1} E_{\{\xi, \rho\} \sim P_r} [f_w(\xi)] - E_{\rho \sim P_g} [f_w(\rho)]$$

Combine the objective of the generative model  $g_{ heta}$  as min  $\mathrm{W}_{1}(P_{r},P_{g})$ 

$$\min_{\theta} \max_{w \in W, \|f_w\|_{I} \le 1} E_{\{\xi, \rho\} \sim P_r}[f_w(\xi)] - E_{\varsigma \sim P_z}[f_w(g_{\theta}(\varsigma))]$$

## Wasserstein-Distance for TPP

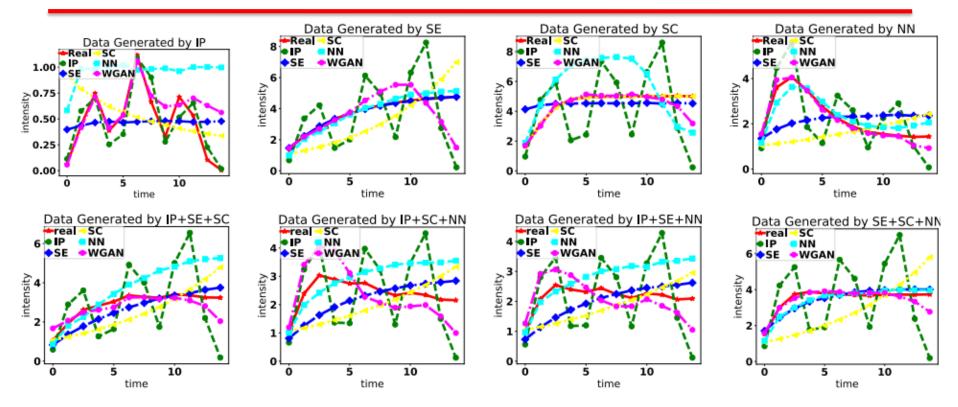

#### Wasserstein-GAN for TPP

Final Objective with penalty to guarantee Lipschitz limitation

$$\min_{\theta} \max_{w \in \mathcal{W}, \|f_w\|_1} \leq_1 \frac{1}{L} \sum_{l=1}^L f_w(\xi_l) - \sum_{l=1}^L f_w(g_\theta(\zeta_l)) - \nu \sum_{l,m=1}^L \frac{|f_w(\xi_l) - f_w(g_\theta(\zeta_m))|}{|\xi_l - g_\theta(\zeta_m)|_\star} - 1 |$$
 min-max discriminator generator Regularization: 1-Lipschitz condition in WGAN

distance between sequences

## Outline

- 1. Introduction of point process
- 2. Classic statistical learning of TPP
- 3. Deep learning for TPP
- 4. Wasserstein adversarial learning for TPP
- 5. Reinforcement learning for TPP
- 6. Embedding for multi-dimensional TPP

# Reinforcement Learning for TPP

- Given a sequence of past events  $s_t = \{t_i\}_{t_i < t}$
- ▶ The stochastic policy  $\pi_{\theta}(a|s_t)$  samples action a as interevent time, where  $t_{i+1} = t_i + a$
- Relation about intensity

$$\lambda_{\theta}(t|s_{t_i}) = \frac{\pi_{\theta}(t - t_i|s_{t_i})}{1 - \int_{t_i}^{t} \pi_{\theta}(\tau - t_i|s_{t_i}) d\tau}$$
 conditional density function f\*

Here regard policy as the

If given a reward function r(t)

$$\pi_{\theta}^* = \arg\max J(\pi_{\theta}) \coloneqq E_{\eta \sim \pi_{\theta}} \left[ \sum_{i=1}^{N_T^{\eta}} r(t_i) \right]$$
 [Li et al, 2018]

[1] Learning temporal point processes via reinforcement learning. In NIPS, 2018

## Reinforcement Learning for TPP

- However, only the expert's sequences are observed
- Solution: Inverse Reinforcement Learning (IRL)
- Given the expert policy  $\pi_E$

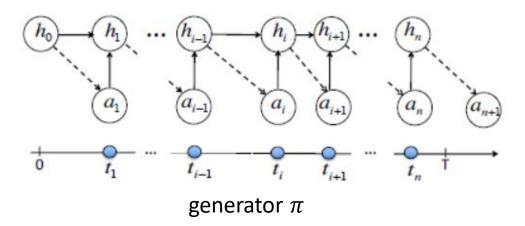

$$r^* = \arg\max\left(E_{\xi \sim \pi_E} \left[\sum_{i=1}^{N_T^{\xi}} r(\tau_i)\right] - \max_{\pi_{\theta}} E_{\eta \sim \pi_{\theta}} \left[\sum_{i=1}^{N_T^{\eta}} r(t_i)\right]\right)$$

The final optimal policy can be obtained by

$$\pi_{\theta}^* = \mathrm{RL} \circ \mathrm{IRL}(\pi_E)$$

# Policy Network

Adopt the recurrent neural network (RNN) to generate the action  $a_i \sim \pi(a|\Theta(h_{i-1})), h_i = \psi(Va_i + Wh_{i-1})$ 

 Common distributions such as exponential and Rayleigh distributions would satisfy such constraint

$$\pi(a|\Theta(h)) = \Theta(h) \cdot \exp(-\Theta(h)a)$$
 or  $\pi(a|\Theta(h)) = \Theta(h) \cdot \exp(-\Theta(h)a^2/2)$ 

### **Reward Function Class**

- ► The reward function directly quantifies the discrepancy between  $\pi_E$  and  $\pi_{\theta}$ , and it guides the optimal policy
- ▶ Choose the reward r(t) in the unit ball in RKHS

$$\phi(\eta) \coloneqq \int_{[0,T)} k(t,\cdot) dN_t^{(\eta)} \qquad \qquad \mu_{\pi_{\theta}} \coloneqq E_{\eta \sim \pi_{\theta}} [\phi(\eta)]$$

feature mapping from data space to R

mean embedding of the intensity in RKHS

Using the reproducing property

$$J(\pi_{\theta}) \coloneqq E_{\eta \sim \pi_{\theta}} \left[ \sum_{i=1}^{N_{T}^{(\eta)}} r(t_{i}) \right] = E_{\eta \sim \pi_{\theta}} \left[ \int_{[0,T)} \langle r, k(t,\cdot) \rangle_{H} dN_{t}^{(\eta)} \right] = \left\langle r, \mu_{\pi_{\theta}} \right\rangle_{H}$$

► Also one can obtain  $J(\pi_{\theta}) = \langle r, \mu_{\pi_E} \rangle_H$ 

#### Reward Function Class

Then, reward function can be obtained by

$$\max_{\|r\|_{H}\leq 1}\min_{\pi_{\theta}}\left\langle r,\mu_{\pi_{E}}-\mu_{\pi_{\theta}}\right\rangle_{H}=\min_{\pi_{\theta}}\max_{\|r\|_{H}\leq 1x}\left\langle r,\mu_{\pi_{E}}-\mu_{\pi_{\theta}}\right\rangle_{H}=\min_{\pi_{\theta}}\max_{\|r\|_{H}\leq 1}\left\|\mu_{\pi_{E}}-\mu_{\pi_{\theta}}\right\|_{H}$$

where 
$$r^*(\cdot | \pi_E, \pi_\theta) = \frac{\mu_{\pi_E} - \mu_{\pi_\theta}}{||\mu_{\pi_E} - \mu_{\pi_\theta}||_H} \propto \mu_{\pi_E} - \mu_{\pi_\theta}$$

▶ **Theorem**: Let the family of reward function be the unit ball in RKHS H, i.e.  $||r||_H \le 1$ , then the optimal policy obtained by solving

$$\pi_{\theta}^* = \arg\min_{\pi_{\theta}} D(\pi_E, \pi_{\theta}, H)$$

where

$$D(\pi_E, \pi_\theta, H) = \max_{\|r\|_{H} \le 1} \left( E_{\xi \sim \pi_E} \left[ \sum_{i=1}^{N_T^{\xi}} r(\tau_i) \right] - E_{\eta \sim \pi_\theta} \left[ \sum_{i=1}^{N_T^{\eta}} r(t_i) \right] \right)$$

### **Reward Function Class**

Finite Sample Estimation. Given L trajectories for expert point processes and M generated by  $\pi_{\theta}$  with embedding  $\mu_{\pi_E}$  and  $\mu_{\pi_{\theta}}$  estimated by their empirical mean

$$\hat{\mu}_{\pi_E} = \frac{1}{L} \sum_{l=1}^{L} \sum_{i=1}^{N_T^{(l)}} k(\tau_i^{(l)}, \cdot) \qquad \hat{\mu}_{\pi_\theta} = \frac{1}{M} \sum_{m=1}^{M} \sum_{i=1}^{N_T^{(m)}} k(t_i^{(m)}, \cdot)$$

▶ Then for any  $t \in [0, T)$ , the estimated optimal reward (without normalization) is

$$\hat{r}^*(t) \propto \frac{1}{L} \sum_{l=1}^{L} \sum_{i=1}^{N_T^{(l)}} k\left(\tau_i^{(l)}, t\right) - \frac{1}{M} \sum_{m=1}^{M} \sum_{i=1}^{N_T^{(m)}} k(t_i^{(m)}, t)$$

## Learning Algorithm

- Learning via Policy Gradient
- ▶ Equivalently optimize  $D(\pi_E, \pi_\theta, H)^2$  instead of  $D(\pi_E, \pi_\theta, H)$

$$\nabla_{\theta} D(\pi_{E}, \pi_{\theta}, H)^{2} = E_{\eta \sim \pi_{\theta}} \left[ \sum_{i=1}^{N_{T}^{(\eta)}} (\nabla_{\theta} \log(\pi(a_{i} | \Theta(h_{i-1})))) \cdot \left( \sum_{i=1}^{N_{T}^{\eta}} \hat{r}^{*}(t_{i}) \right) \right]$$

▶ After sampling M trajectories from the current policy, use one trajectory for evaluation and the rest M-1 samples to estimate reward function.

# Algorithm and framework

Algorithm RLPP: Mini-batch Reinforcement Learning for Learning Point Processes

- 1. Initialize model parameters  $\theta$ ;
- 2. For number of training iterations do
  - Sample minibatch of L trajectories of events  $\{\xi^{(1)}, \ldots, \xi^{(L)}\}$  from expert policy  $\pi_E$ , where  $\xi^{(l)} = \{\tau_1^{(l)}, \ldots, \tau_{N_{\sigma}^{(l)}}^{(l)}\};$
  - Sample minibatch of M trajectories of events  $\{\eta^{(1)}, \dots, \eta^{(M)}\}$  from learner policy  $\pi_{\theta}$ , where  $\eta^{(m)} = \{t_1^{(m)}, \dots, t_{N_T}^{(m)}\};$
  - Estimate policy gradient  $\nabla_{\theta} D(\pi_E, \pi_{\theta}, \mathcal{H})^2$  as

$$\nabla_{\theta} \frac{1}{M} \sum_{m=1}^{M} \left( \sum_{i=1}^{N_{T}^{(m)}} \hat{r}^{*}(t_{i}^{(m)}) \log p_{\theta}(\eta^{(m)}) \right)$$

where  $\log p_{\theta}(\eta^{(m)}) = \sum_{i=1}^{N_T^n} (\log \pi_{\theta}(a_i|\Theta(h_{i-1})))$  is the log-likelihood of the sample  $\eta^{(m)}$ , and  $r^*(t_i^{(m)})$  can be estimated by L expert trajectories and (M-1) roll-out samples without  $\eta^{(m)}$ 

$$\begin{split} \hat{r}^*(t^{(m)}) &= \frac{1}{L} \sum\nolimits_{l=1}^{L} \sum\nolimits_{i=1}^{N_T^{(l)}} k(\tau_i^{(l)}, t) \\ &- \frac{1}{M-1} \sum\nolimits_{m'=1, m' \neq m}^{M} \sum\nolimits_{j=1}^{N_T^{(m')}} k(t_j^{(m')}, t); \end{split}$$

Update policy parameters as

$$\theta \leftarrow \theta + \alpha \nabla_{\theta} D(\pi_E, \pi_{\theta}, \mathcal{H})^2$$
.

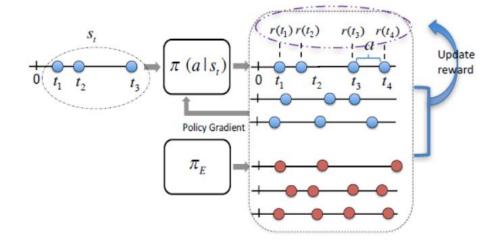

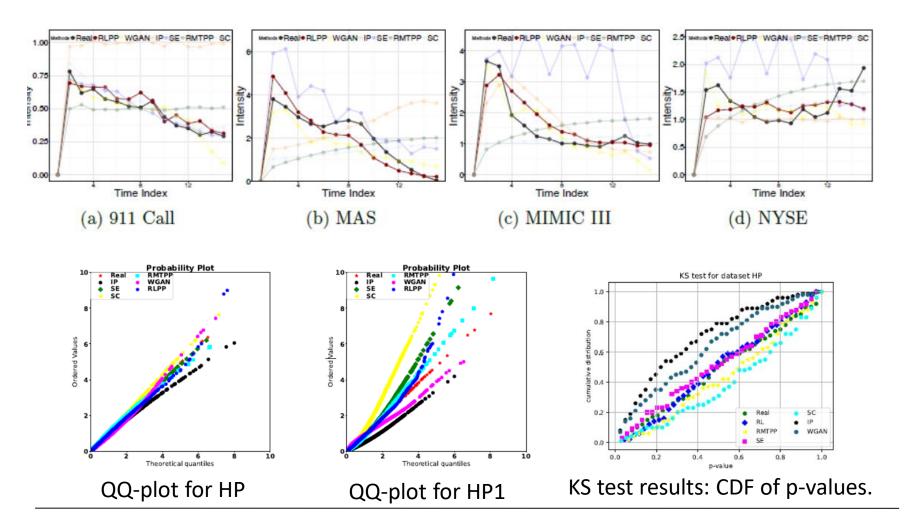

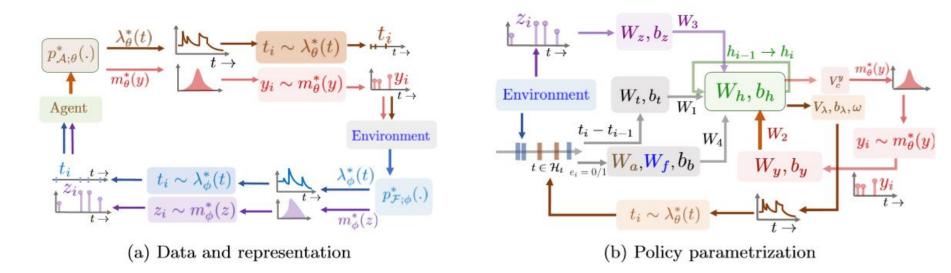

Illustration of the modeling framework.

## Experiments

[Upadhyay et al 2018] use RL to model the marked point process.

Deep reinforcement learning of marked temporal point processes. In NIPS, 2018

### Other Works for RL in Pont Process

► [Wu et al 2019] cluster the sequences with different temporal patterns into the underlying policies

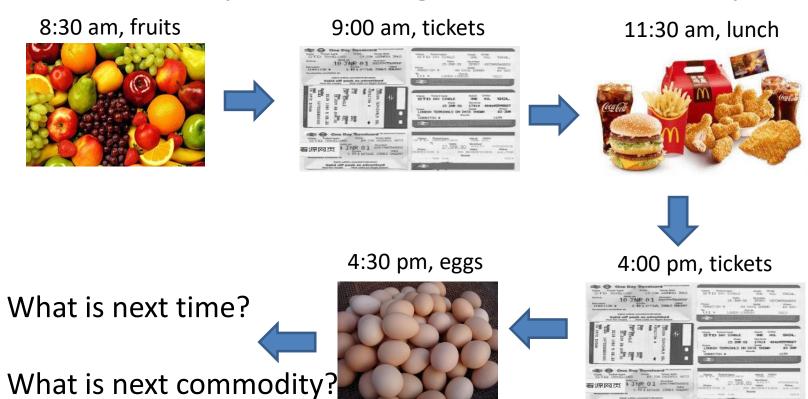

Reinforcement Learning with Policy Mixture Model for Temporal Point Processes Clustering, https://arxiv.org/abs/1905.12345

### Outline

- 1. Introduction of point process
- 2. Classic statistical learning of TPP
- 3. Wasserstein adversarial learning for TPP
- 4. Reinforcement learning for TPP
- 5. Embedding for multi-dimensional TPP

# Background

### Someone buy something online. For example,

## Embedding for multi-dimensional TPP

Main idea: marker  $\Longrightarrow$  node (commodity) **Directed Graph** Graph representation with node embedding for events Node Connection Indirect Influence Event propagation Event propagation Sequence 1 Sequence 2 [Wu et al 2019]

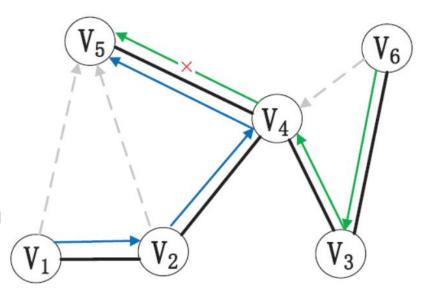

## Graph node embedding by MLE (pretrain)

- Graph representation for Directed Graph (pre-trained)
- Capture the edge and node information
- Edge reconstruction probability → MLE

$$p(v_i, v_j) = \frac{1}{1 + \exp(-\boldsymbol{y}_i^{ST} \boldsymbol{y}_j^e)}$$

- There may be indirect influence form  $V_1$  to  $V_5$
- Get the node representation

$$\mathbf{y}_i = \{\mathbf{y}_i^s, \mathbf{y}_i^e\}$$

# **Graph biased TPP**

- GBTPP for events (nodes)
- $ightharpoonup h_n$  is the hidden units

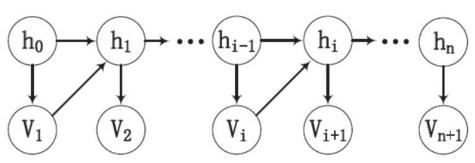

$$\begin{aligned} & \boldsymbol{h}_{n-1} = \max\{W^{v}v_{n-1} + W^{v}y_{n-1} \\ &+ W^{t}t_{n-1} + W^{h}h_{n-2} + b_{h}, 0\} \end{aligned}$$

Graph bias term

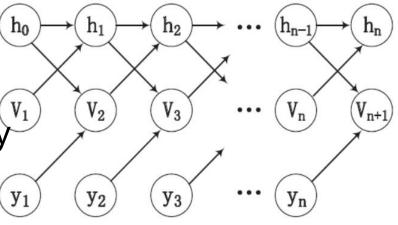

$$b(\boldsymbol{h}_{n-1}, \boldsymbol{y}_n, \boldsymbol{y}_k) = ReLu(\boldsymbol{U}_{n,:}^h \boldsymbol{h}_{n-1}) p(\boldsymbol{y}_n, \boldsymbol{y}_k)$$

Node propagation probability

$$= \frac{P\left(v_{n+1} = k | \boldsymbol{h}_{n-1}, \boldsymbol{y}_{n}\right)}{\sum_{k=1}^{V} \exp\left(\boldsymbol{V}_{k,:}^{h} \boldsymbol{h}_{n-1} + b(\boldsymbol{h}_{n-1}, \boldsymbol{y}_{n}, \boldsymbol{y}_{k}) + b_{k}^{h}\right)}$$

Traditional deep TPP

GBTPP based on  $\{y_i\}$ 

## **Graph biased TPP**

For conventional intensity function

$$\lambda^*(t) = \exp(\mathbf{v}^{h\mathrm{T}} \cdot \mathbf{h}_{n-1} + \mathbf{v}^{y\mathrm{T}} \cdot \mathbf{y}_n + w^t(t-t_j) + b)$$

past history direct node influence influence kernel intensity

#### Density function

$$f^{*}(t) = \lambda^{*}(t) \exp(-\int_{t_{j}}^{t} \lambda^{*}(\tau) d\tau)$$

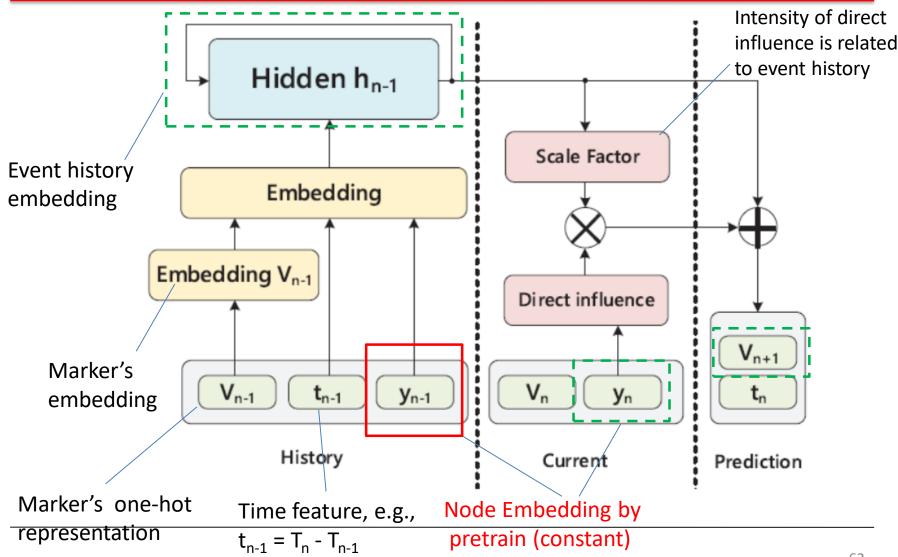

$$= \exp\{\mathbf{v}^{hT} \cdot \mathbf{h}_{n-1} + \mathbf{v}^{yT} \cdot \mathbf{y}_{n} + w(t - t_{j}) + b - \frac{1}{w} (\exp(\mathbf{v}^{hT} \cdot \mathbf{h}_{n-1} + \mathbf{v}^{yT} \cdot \mathbf{y}_{n} + \mathbf{v}^{yT} \cdot \mathbf{y}_{n} + w(t - t_{j}) + b) - \exp(\mathbf{v}^{hT} \cdot \mathbf{h}_{n-1} + \mathbf{v}^{yT} \cdot \mathbf{y}_{n} + b))\}$$

$$= \exp\{\mathbf{v}^{hT} \cdot \mathbf{h}_{n-1} + \mathbf{v}^{yT} \cdot \mathbf{y}_{n} + w(t - t_{j}) + b - \exp(\mathbf{v}^{hT} \cdot \mathbf{h}_{n-1} + \mathbf{v}^{yT} \cdot \mathbf{y}_{n} + b))\}$$

$$= \exp\{\mathbf{v}^{hT} \cdot \mathbf{h}_{n-1} + \mathbf{v}^{yT} \cdot \mathbf{y}_{n} + b - \frac{1}{w} (\exp(\mathbf{v}^{hT} \cdot \mathbf{h}_{n-1} + \mathbf{v}^{yT} \cdot \mathbf{y}_{n} + b))\}$$
